Department of Computer Science with Artificial Intelligence and Data Science, KPR College of Arts Science and Research, Coimbatore, Tamil Nadu, India

***Abstract*—Many villages still keep records in paper registers, which makes information slow to find, easy to lose and hard to update. This paper presents a Village Development Information System that stores village data in one digital platform. The system manages population, education, healthcare, agriculture, government schemes, citizen complaints and development projects through a secure administrator login. It is built with a web front end, a Python server and a relational database. The design reduces paperwork, speeds up retrieval and supports monitoring of project progress. The paper describes the problem, the proposed modules, the architecture, the requirements and the database design, and outlines future enhancements.**

Keywords—village information system; rural development; e-governance; web application; database

I. INTRODUCTION

Villages play an important role in national development because many people depend on agriculture, local employment, education, healthcare and other basic facilities. For proper development, accurate and updated information about the village is essential. Traditionally, village records are maintained manually in registers and paper documents. This takes more time and effort, makes old information difficult to find or update, and carries the risk of lost or damaged records [1].

A Village Development Information System is a digital system designed to collect, store, manage and provide important information about a village. It can maintain details about population, education, healthcare, agriculture, employment, water supply, electricity, roads, sanitation, transportation and other public facilities. Information systems of this kind have been proposed as tools for rural governance and for achieving sustainable development goals [2].

The system can also provide information about government schemes and welfare programs, and it can include a complaint and feedback module so that residents can report problems with roads, water, electricity, waste management or other public facilities. This helps administrators understand the needs of the people and take suitable action. The main purpose of the system is to reduce paperwork, save time, improve data management and give easy access to village information, while improving communication between the people and the administration.

The rest of this paper is organized as follows. Section II reviews related work, Section III describes the research material and method, Sections IV to VII explain the problem, objectives, scope and existing system, Sections VIII and IX describe the proposed system and its modules, Sections X to XX cover technologies, requirements, design, implementation, security, testing, discussion and adoption challenges, and Sections XXI to XXIII present advantages, limitations, future work and conclusions.

II. RELATED WORK

Village information systems are widely seen as a critical factor in rural development because they allow the government to identify the direction of village development in line with the needs and resources of the village [2]. Studies of their implementation report recurring challenges: a lack of regulations at the local level, limited human resource capacity, weak information technology infrastructure and pilot applications that do not perform well. Recommended responses include local regulations, investment in technology infrastructure and training of staff.

These findings show that a village information system must be simple to use, inexpensive to run and easy to maintain. The system in this paper therefore uses common, freely available tools and a small number of clearly separated modules, so that village staff with basic digital knowledge can operate it.

III. RESEARCH MATERIAL AND METHOD

The study uses information collected from sources related to village administration and rural development, such as books, academic articles, government reports, websites and existing information systems. Discussions with villagers and local administrative staff help identify common problems and requirements. The collected information about population, education, healthcare, agriculture, drinking water, roads, sanitation, electricity, employment, government schemes and public facilities is organized and analysed to find the limitations of the manual system and to design a computerized one.

The work follows five steps: requirement collection, analysis of the existing system, design of the modules and database, implementation with the selected technologies, and testing. The technologies HyperText Markup Language (HTML), Cascading Style Sheets (CSS), JavaScript, Python and MySQL were studied for building the proposed system, because together they are suitable for a simple, reliable and user-friendly application.

Information technology provides a better way to manage village information. A computerized system can store large amounts of data in a structured database, and the data can be searched, updated and retrieved whenever required. The proposed system gives a centralized platform that administrators use to maintain records and citizens use to learn about the facilities available in their village. It shows how web technologies and database systems can be combined into a useful application for rural development [3].

IV. PROBLEM STATEMENT

Many villages still depend on manual methods for important information. Paper records need more storage space and are difficult to search and update. The major problems are manual maintenance of records, difficulty in finding information quickly, repeated data entry, the possibility of losing records, difficulty in updating information, lack of centralized information, limited communication between villagers and administrators, difficulty in monitoring development projects, lack of proper complaint management and time-consuming report preparation.

The Village Development Information System is proposed to solve these problems by providing a centralized digital information system.

V. OBJECTIVES

The main objective is to develop a simple and useful system for managing village development information. The specific objectives are to store village information digitally, reduce paper-based record maintenance, provide information quickly, manage citizen details, maintain education and healthcare information, store agriculture-related information, provide information about government schemes, manage public complaints, monitor village development projects, generate useful reports, improve communication between citizens and administrators and support better village development planning.

VI. SCOPE OF THE PROJECT

The system can be used by village administrators and citizens. Its scope covers six areas. Basic village information such as name, location, population and facilities can be stored. Education information about schools, students, teachers and educational facilities can be maintained. Healthcare details about hospitals, health centres, doctors and healthcare facilities can be stored. Agriculture information about crops, farmers, irrigation and agricultural activities can be managed. Information about government welfare schemes can be provided. Citizens can submit complaints about roads, water, electricity, sanitation and other services.

VII. EXISTING SYSTEM

In the existing system, village information is kept in manual records, registers, files and separate documents. This leads to more paperwork, difficulty in searching records, loss or damage of data, slow updating, duplicate records, difficult report generation, information that is not available quickly and poor monitoring of development activities. For example, to find information about one development project, an administrator may have to search through many files, which wastes time and effort. A computerized system is therefore useful for managing village information. Table I compares the existing and proposed systems.

TABLE I. EXISTING AND PROPOSED SYSTEM

Aspect	Existing system	Proposed system
Storage	Paper registers and files	Centralized database
Searching	Slow, manual	Quick, by search
Updating	Time-consuming	Fast and easy
Duplicate data	May occur	Reduced
Complaints	No proper handling	Submitted and tracked
Reports	Difficult to prepare	Generated by system
Monitoring	Difficult	Project status shown

VIII. PROPOSED SYSTEM

The proposed system is a centralized digital platform that stores information in a database and lets authorized users add, update, view and manage records. Its features are a simple user interface, digital record management, a centralized database, easy searching, faster data updating, citizen complaint management, government scheme information, development project monitoring, secure administrator login and report generation.

Two kinds of users work with the system. The administrator logs in, manages village records, publishes scheme information, records project progress and updates the status of complaints. Citizens view village facilities, read about government schemes and submit complaints. The proposed system reduces manual work and improves the efficiency of village administration.

IX. SYSTEM MODULES

The system is divided into the modules listed in Table II. The administrator module lets the administrator log in and manage village information. The village information module stores basic village details. The education, healthcare and agriculture modules hold the information of those sectors, and the complaint module lets citizens submit complaints that administrators can track.

TABLE II. SYSTEM MODULES AND FUNCTIONS

Module	Main functions
Administrator	Login, manage all village records, update complaint status
Village information	Store name, district, population, area, panchayat details, facilities
Education	Schools, students, teachers, educational facilities
Healthcare	Hospitals, health centres, doctors, medical facilities
Agriculture	Farmers, crops, irrigation, agricultural activities
Government scheme	Scheme details, eligibility, benefits, documents, contacts
Complaint	Citizens submit complaints, administrators track them
Development project	Project details, dates, location, department, status

Government scheme module. Government schemes provide financial and social support to people, but people may not always know about the schemes available to them. This module gives the scheme name, description, eligibility, benefits, application procedure, required documents and contact information. The administrator can add new schemes and update existing information when necessary, which helps citizens understand the available government services.

Development project module. Village development includes road construction, street lighting, water supply, drainage, sanitation, school development, healthcare facilities, community buildings and agricultural facilities. This module helps administrators keep the project name, description, starting date, expected completion date, location, responsible department and status. The status is shown as Pending, Ongoing or Completed, so progress can be seen at a glance.

X. TECHNOLOGIES USED

The front end uses HTML to create the structure of the web pages, CSS to design and style them and JavaScript to add interactive features and validation. The back end uses Python to build the server-side application and process user requests. The database is MySQL, which stores and manages village-related data. The basic architecture is user, then HTML, CSS and JavaScript, then Python, then the MySQL database, as shown in Fig. 1. This combination is suitable for a beginner-friendly information system.

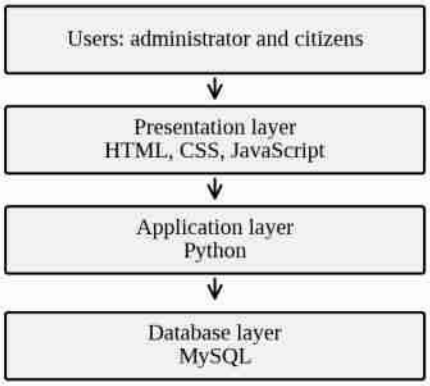

Fig. 1. Three-layer architecture of the system

XI. SYSTEM REQUIREMENTS

The system does not need expensive hardware, so an ordinary computer is enough for development and testing. The hardware and software needed are listed in Table III.

TABLE III. HARDWARE AND SOFTWARE REQUIREMENTS

Type	Requirement
Hardware	Computer or laptop, minimum 4 GB memory, keyboard, mouse, hard disk or solid state drive, internet connection
Software	Windows or Linux, web browser, Visual Studio Code, Python, MySQL, Python database connector, local server

XII. DATABASE DESIGN

The database has six main tables, listed in Table IV. One village has many projects and many beneficiaries, one project has many resources and many progress updates, and users manage and update the system. These relationships are shown in Fig. 2. The design can be implemented directly in MySQL.

TABLE IV. MAIN DATABASE TABLES

Table	Main fields

Village	Village ID, name, district, population
Project	Project ID, name, village ID, start date, end date, status
Beneficiary	Beneficiary ID, name, village ID, contact, address
Resources	Resource ID, project ID, name, quantity, cost
Progress	Progress ID, project ID, update date, percentage, remarks
User	User ID, name, username, password, role

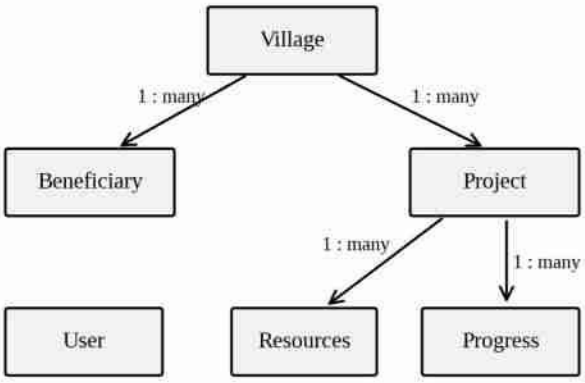

Fig. 2. Relationships between the database tables

The Beneficiary table links each person to a village. The Resources table records the quantity and cost of what each project uses, and the Progress table records the update date, percentage completed and remarks, so that the history of every project can be traced.

XIII. SYSTEM DESIGN

The system follows a simple three-layer structure. The presentation layer is the user interface built with HTML and CSS. The application layer is written in Python and performs adding, updating, deleting and retrieving of information. The database layer is MySQL, which stores all information securely in different tables.

The working flow, shown in Fig. 3, is user login, dashboard, module selection, data entry or viewing, Python processing, MySQL database and display of the result. This structure makes the system easier to understand and maintain, because each layer can be changed without disturbing the others.

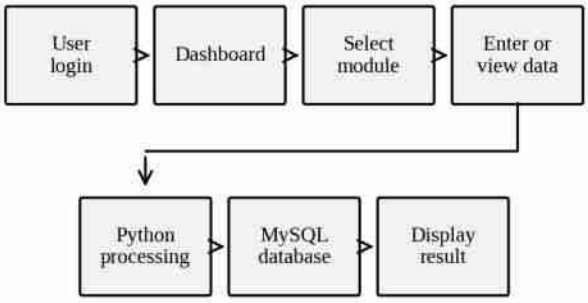

Fig. 3. Working flow of the system

XIV. FUNCTIONAL REQUIREMENTS

Functional requirements describe what the system should do. The system should allow administrator login, display a dashboard, add village information, update village information, delete incorrect information, display education details, display healthcare information, store agriculture information, display government schemes, accept citizen complaints, update complaint status, store development project details, search information, generate reports and log out securely. These functions help the administrator manage village development information effectively.

XV. NON-FUNCTIONAL REQUIREMENTS

Non-functional requirements describe the quality of the system and are summarized in Table V.

TABLE V. NON-FUNCTIONAL REQUIREMENTS

Quality	**Requirement**
Security	Only authorized administrators use management functions
Usability	Simple and easy-to-understand interface
Performance	Quick response to searches
Reliability	Information stored properly and available when required
Maintainability	Easy to update and maintain
Scalability	More modules and information can be added

XVI. IMPLEMENTATION

The administrator first logs in with a username and password and reaches the dashboard, from which every module can be opened. In each module the administrator can add a new record, update an existing one, delete incorrect information or search for a record. Every action is sent to the Python application, which checks the input and then reads or changes the MySQL database. The result is shown on the same page, so the administrator immediately sees the effect of the change.

A complaint is handled in steps. A citizen enters the problem, such as a damaged road, a water shortage or a power failure, together with the location. The complaint is stored in the database, the administrator sees it on the dashboard, and the status is updated as action is taken so that the citizen can follow it. In the same way, each development project is stored with its dates and status, and progress updates with the percentage completed are added over time. Table VI summarizes what each type of user can do.

TABLE VI. USER ROLES AND PERMITTED ACTIONS

User	**Permitted actions**
Administrator	Log in, add, update and delete records, publish schemes, record project progress, update complaint status, generate reports, log out
Citizen	View village facilities, read scheme information, submit complaints, check information on projects

XVII. SECURITY AND DATA MANAGEMENT

Only authorized administrators are allowed to reach the management functions, so every such page requires a successful login, and the role stored in the User table decides what a user may do. Passwords should be stored in protected form and never as plain text. Citizens can read public information and submit complaints but cannot change records.

Reliable data management also needs regular backups of the database, so that records are not lost if the computer fails, and validation of every form so that wrong or incomplete data is not stored. These measures answer the main fear of manual record keeping, which is the loss or damage of records, and they keep the information accurate over time.

XVIII. TESTING

The system is tested at three levels. Each module is first tested alone to check that records can be added, updated, deleted and searched correctly. The modules are then tested together to check that data moves correctly between the interface, the Python application and the database. Finally, administrators and citizens try the system to confirm that it is easy to use and meets the functional requirements. Because incorrect data entered by users affects the results, input validation with JavaScript and Python is applied to every form.

XIX. DISCUSSION

Each problem identified in Section IV is answered by a feature of the proposed system. Manual maintenance and loss of records

are answered by digital record management and a centralized database. Difficulty in finding and updating information is answered by search and quick updating. Repeated data entry is reduced because information is stored once and reused. Limited communication between villagers and administrators is answered by the scheme and complaint modules, and difficulty in monitoring projects is answered by the development project module with its status and progress updates. Time-consuming report preparation is answered by report generation from the stored data.

The system is intentionally simple. It uses common tools that run on an ordinary computer, so a village office can adopt it without large investment. At the same time its modular design allows new sections to be added later, which is important because the needs of a village change over time.

XX. ADOPTION CHALLENGES

A good design alone does not guarantee success, because the use of a village information system depends on people and resources. The studies discussed in Section II found that the main obstacles are the lack of local regulations, limited human resource capacity, weak technology infrastructure and applications that perform poorly in pilot use [2]. Table VII links each of these challenges to an action that fits the proposed system.

TABLE VII. ADOPTION CHALLENGES AND ACTIONS

Challenge	**Recommended action**
Lack of local regulations	Formulate local regulations for the system
Limited staff capacity	Train and develop village staff
Weak technology infrastructure	Invest in basic equipment and connectivity
Poorly performing pilot applications	Test and improve the application before wide use

Training deserves special attention. Administrators need to learn how to enter data correctly, how to update complaint and project status and how to take backups, while citizens need to know how to find information and submit a complaint. Short practical sessions, a simple user guide and a clear interface keep the learning effort low. If the system is introduced step by step, starting with village information and complaints and then adding the other modules, the staff can gain confidence before the whole system is used.

The expected outcome is a village office that spends less time on paperwork, answers questions about facilities and schemes quickly, reacts to complaints in an organized way and can show the status of every development project from one place.

XXI. ADVANTAGES AND LIMITATIONS

The advantages are that the system saves time, reduces paperwork, makes searching easy, keeps data in one place, makes updating easy, helps monitor development projects, improves information sharing, helps administrators make better decisions, keeps organized records and reduces duplicate data.

The limitations are that a computer or mobile device is required, users need basic digital knowledge, internet access may be required for an online version, the database needs regular maintenance and incorrect data entered by users affects the results. Despite these limitations, the system is an effective method for managing village information.

XXII. FUTURE ENHANCEMENTS

Future features may include a mobile application, online citizen registration, short message notifications, online complaint tracking, multilingual support, location and map integration, online government scheme applications, digital document upload, data analytics, dashboard charts, automatic report generation, a cloud database and improved authentication. Artificial intelligence could also be used to analyse village data and help identify important development needs.

XXIII. CONCLUSION

The Village Development Information System is a useful digital system for managing information about education, healthcare, agriculture, government schemes, complaints and development projects. It provides a centralized platform for storing and accessing this information, reduces the difficulties of paper records and makes information management faster and more organized.

By using HTML, CSS, JavaScript, Python and MySQL, a simple and effective system can be developed. The project can help administrators manage village information and support better development planning, and it makes important information more easily available to citizens. In the future the system can be expanded with mobile applications, maps, notifications, multilingual support, cloud technology and data analytics. It can therefore play an important role in creating a more organized and digitally connected village administration.
